Abstract
Non-linearity in dynamics of legged robots is so strong that control of them is a quite hard problem. An efficiency of lower-level modelization of robots based on the COG has been confirmed both qualitatively and quantitatively. However, the large gap between such lower-level model and precise model often causes the difficulty. In this paper, COG Jacobian, which relates the whole-body motion to COG motion, is proposed to handle the legged robot. It is also effective for ZMP manipulation which functions as a key for stable and responsive motion. Two applications of it, motion stabilization method based on DT AD(Dual Term Absorption of Disturbance) and VIIP(Variable Impedant Inverted Pendulum) model control, are introduced.

1. Introduction
Complexity of humanoids as dynamical systems lies upon the two issues, namely, i) they are multibody systems with a number of links. Moreover, they are nonholonomic systems in nature, due to having underactuated links. And ii) the structure varies through the interaction with the environment[1]. An appropriate lower-level modelization, therefore, helps to handle such complicated systems.

Miyazaki et al.[2] separated modes of a biped system into slow and fast modes based on singular perturbation. Furusho et al.[3] showed that the behavior of a biped is approximated only by slow modes with a good precision to control with strong local feedback control. The slow modes revealed in these studies are similar to that of an inverted pendulum in accordance with the fact that the COG of the system is located above the working point of external force. Various controlling methods with lower-level models based on this idea have been proposed so far [4, 5, 6].

However, the large gap between the lower-level model and the precise model is the bottleneck since COG is a highly-redundant against the whole joint, it is difficult to resolve the required COG motion into the whole-body motion uniquely. Kajita et al.[4] substituted displacement of the COG for that of trunk, which is only applicable for robots with ignorably light legs.

In this paper, the concept and calculation method of COG Jacobian of legged systems is proposed. Thanks to it, COG velocity can be controlled just as manipulator endpoint[7]. Tamiya et al.[8] obtained it numerically by quasi-gradient using a kinematic model. It requires a large amount of computation. Furthermore, it does not solve the structure-varying feature. All these difficulties are overcome by the proposed.

It also enables an easy manipulation of the ZMP[9] which is significant in the control of legged systems. The stabilization and responsive motion of them are realized through the manipulation. Two typical applications, motion stabilization method based on DT AD(Dual Term Absorption of Disturbance) and VIIP(Variable Impedant Inverted Pendulum) model control, are introduced to show the efficiency of it.

2. Derivation of COG Jacobian
A legged robot is modelized as is figured in Fig.1; the root link of the robot is connected with the inertia frame $\Sigma_W$ via a virtual 6-DOF pair, and extremeties branch out of the root. We express the frame bound to the root for $\Sigma_0$ hereafter. A velocity vector of an arbitrary point $p$ and a rotational velocity of link $k$, $\omega_k$ can be expressed as follows.

$$\dot{p} = \dot{p}_0 - (R_0^0 p) \times \omega_0 + R_0^0 \dot{p} \quad (1)$$
$$\omega_k = \omega_0 + R_0^0 \omega_k \quad (2)$$

where $R_0$ is an attitude transportation matrix from $\Sigma_0$ to $\Sigma_W$, $p_0$ is the original point and $\omega_0$ is the rotational velocity of $\Sigma_0$ with respect to $\Sigma_W$, $\omega_k$ is a relative rotational velocity of link $k$ and $\dot{p}$ is a relative position vector of $p$ with respect to $\Sigma_0$. Using the method by
Orin et al. [10], Jacobians $\dot{0}J_ωk$ and $\dot{0}J$ which satisfy the following (3)(4) are obtained.

\begin{align}
\dot{0}ω_k &= \dot{0}J_ωk\dot{θ} \\
\dot{0}p &= \dot{0}J\dot{θ}
\end{align}

From Eq.(1), the COG velocity $\dot{p}_G$ is expressed as:

$$\dot{p}_G = \dot{p}_0 - (R_0^0p_G) \times \omega_0 + R_0^0\dot{p}_G$$

$\dot{0}p_G$ is calculated as:

$$\dot{0}p_G = \sum_{k=0}^{n} m_k 0p_{Gk} \equiv \sum_{k=0}^{n} m_k 0J_{Gk}\dot{θ}$$

where $n$ is the number of links, $m_k$ is the mass of link $k$, $0p_{Gk}$ is the COG of link $k$ with respect to $Σ_0$, $θ$ is the whole joint angle, and $0J_{Gk}$ is COG Jacobian of each link $k$. From Eq.(6), we define $0J_G$ as follows.

$$0J_G = \sum_{k=0}^{n} m_k 0J_{Gk}$$

Suppose that the link $F$ is fixed in the inertia frame and sufficient friction force prevents it from slipping, both the linear and rotational velocity of link $F$ with respect to $Σ_W$ are zero. Thus, from Eq.(2)(1), we get:

$$\omega_F = 0 ⇔ \omega_0 = -R_0^0\omega_F$$

$$\dot{p}_F = 0 ⇔ \dot{p}_0 = (R_0^0p_F) \times \omega_0 - R_0^0\dot{p}_F$$

where $p_F$ is a certain point in link $F$. Consequently,

$$\omega_0 = -R_0^0\dot{0}J_ωF\dot{θ}$$

$$\dot{p}_0 = -R_0^0(\dot{0}p_F \times (0J_ωF\dot{θ}) + 0J_F\dot{θ})$$

$\dot{0}J_ωF$ and $\dot{0}J_F$ are obtained from Eq.(3)(4). Putting them into Eq.(5), we get:

$$\dot{p}_G = R_0^0[0J_G - 0J_F + ([0p_G - 0p_F] \times 0J_ωF) \dot{θ}$$

where $[v \times]$ corresponding to an arbitrary vector $v$ is an equivalent matrix to the outer product with $v$. From Eq.(12), COG Jacobian $J_G$ can be defined by

$$J_G = R_0^0[0J_G - 0J_F + ([0p_G - 0p_F] \times 0J_ωF)$$

and it also means that the COG velocity can be related explicitly to the whole joint angle velocity, apparently as the linear summation of it. This fact helps to treat it as a simple linear equational constraint.

3. A Pattern-based Motion Control with DTAD method [11]

3.1. Outline

A pattern-based approach is the easiest way to reduce the difficulty on the control of humanoid robots: operators may prepare proper motion trajectories to accomplish the task, considering the complicated constraints in advance, and simply get robots to replay them. This idea requires online stabilization in addition to designing of the trajectories [12, 13], since various unpredictable factors often make motion of robots unstable in the real world. Though several methods [14, 13, 5] have been proposed, they still have limitation problems of applicability. A stabilization method proposed in this section consists of both the short-term and long-term absorption of disturbance, and thus we named it DTAD (Dual Term Absorption of Disturbance) method. It is applicable for a variety of motion of humanoid robots.

Absorption of Unpredicted Force

Postural Recovery

Figure 2: The two basic schemes to balance

Two important schemes exist on the stabilization of legged motion as is figured in Fig.2, that is, i) absorption of unpredicted force, and ii) robust compensation
of the postural error. The former item deforms postural
pattern, while the latter deforms force pattern, so that
they obviously conflict with each other. Human-beings
seem to realize such the conflicting schemes with skill-
ful whole-body cooperation. It is expected, therefore,
that the implementation of similar function leads to re-
liable operations of humanoid robots.

Suppose that motion of robots are described by joint
angle \( \theta \), the COG \( p_G = [x_G, y_G, z_G]^T \), the ZMP
\( p_Z = [x_Z, y_Z, z_Z]^T \), and the vertical reaction force
\( f_z \) (z-axis coincides with the direction against grav-
ity), and that the command set of the above parameters
\( \theta_{cmd}, x_G, x_Z, f_z \) are given without physical
inconsistency. The method proposed calculates as
close referential value of \( \theta, \theta_{ref} \) which achieves the
two conflicting schemes to \( \theta_{cmd} \) as possible.

### 3.2. Short-term Absorption of Disturbance

Unpredicted force often makes motion of robots unsta-
able. Thus, absorption of it is required to avoid short-
term crisis. It is achieved by letting \( \theta_{ref} \) coincide with
\( \theta_{cmd} \) and \( f_z \) respectively. It also works to
keep stable contact between the robot and the ground.
This should be accomplished in quite short term and we
call it short-term absorption of disturbance.

Assuming a mass-concentrated model, the equation of
motion is approximately expressed as:

\[
\begin{align}
\dot{x}_G &= \omega^2 (x_G - x_Z) \\
\dot{y}_G &= \omega^2 (y_G - y_Z) \\
\dot{z}_G &= f_z/m - g
\end{align}
\]

where \( m \) is the total mass of the robot, \( g \) is the accel-
eration of gravity, and \( \omega^2 \) is defined by

\[ \omega^2 \equiv \frac{f_z}{m(z_G - z_Z)} \]  

Although this ignorance of the inertia of each link
makes it less accurate, the amount of computation is
reduced enough to be suitable for real-time control.

Giving the acceleration in Eq.(14)\(~16\) with substitut-
ing \( \theta_{ref} \) and \( \theta_{cmd} \) for \( \theta_{cmd} \) and \( \theta_{ref} \) respec-
tively, short-term absorption of disturbance is achieved.

### 3.3. Long-term Absorption of Disturbance

Modification of acceleration in the previous section
3.2. deforms the postural pattern. In order to recover
it, the position of COG should be put back to the de-
sired position. It is realized by substituting \( \theta_{cmd} \) and
\( f_z \) for the following \( \theta_{ref} \) and \( \theta_{cmd} \) respectively.

\[
\begin{align}
\dot{\theta}_{ref} &= \dot{\theta}_{cmd} + \Delta \theta \equiv \dot{\theta} + \Delta \theta \\
\dot{x}_Z &= \dot{x}_Z - D_x \Delta x_G + D_z \Delta f_z \\
\dot{y}_Z &= \dot{y}_Z - D_y \Delta y_G + D_z \Delta y_{cmd} \\
\dot{z}_Z &= \dot{z}_Z - \Delta f_z + m (K_x \Delta x_G + D_z \Delta x_{cmd})
\end{align}
\]

where \( K_x \) and \( D_z \) are the proportional and differen-
tial gains respectively, and \( \Delta \theta_{cmd} \) is defined by

\[
\Delta \theta_{cmd} \equiv \theta_{cmd} \theta_{cmd} - \theta_{ref}
\]

Since the ZMP has to be located in a certain region
and the ground reaction force has to be positive, when
\( \theta_{ref} \) and \( \theta_{cmd} \) don’t satisfy these conditions, the
nearest value within the region is chosen instead.

This procedure should be accomplished in rather long
term than short-term absorption of disturbance
so that we call it long-term absorption of disturbance.
Conclusively, \( \theta_{ref} \) is decided from Eq.(14)\(~16\)
and (18)\(~20\). Integrating it, we get \( \theta_{ref} \).

### 3.4. COG Control with Whole-body Cooperation

\( \theta_{ref} \) should be as close value to \( \theta_{cmd} \) as possible. This
problem can be interpreted to the following.

\[
\begin{align}
\frac{1}{2} \left( \begin{array}{c} \dot{\theta} - \dot{\theta}_{ref} \\
\end{array} \right)^T W \left( \begin{array}{c} \dot{\theta} - \dot{\theta}_{ref} \\
\end{array} \right) \rightarrow \text{min.}
\end{align}
\]

subject to

\[
\begin{align}
J_G \dot{\theta} &= \dot{\theta}_{ref} \\
J_C \dot{\theta} &= c
\end{align}
\]

where \( W \) is the weighting matrix and \( J_C \) means the
constraint required for the task execution.

(22) can be solved as:

\[
\dot{\theta} = \dot{\theta}_{cmd} + W^{-1} J^T U (J W^{-1} J^T)^{-1} v
\]

Each joint angle actuator is controlled according to
\( \dot{\theta} \). Then, the whole-body motion of the robot is
achieved. Giving an adequate \( W \), an effective whole-
body cooperative motion stabilization is achieved.

### 3.5. Simulation

We verified the method in some simulations, using a
model of HOAP-1(Fujitsu Automation Ltd.). Kinemat-
ic structure, size and mass of the robot are shown in
Fig.5. Fig.3 is a snapshot of walking motion under
impulsive disturbance. Fig.4 shows the loci of each
component of the COG. These figure the method pro-
posed works as is expected, stabilizing the motion with
the whole-body cooperation.
4. Motion Control based on VIIP [15]

4.1. Outline

Though pattern-based approaches can reduce the difficulty in realizing a variety of motion, they are less promising in the real environment filled with unpredictable factors. A controlling method for much more responsive motion is required. Previous trials[16, 6], however, commonly suffer from the complexity of the problem. VIIP(Variable Impedant Inverted Pendulum) model control can give a solution of it.

One can see from Eq.(14) and (15) that legged robots have similar dynamics with an inverted pendulum whose supporting point is equivalently located at the ZMP. Thus, the COG can be controlled as well as an inverted pendulum through ZMP manipulation.

The supporting point of an inverted pendulum can be manipulated directly, while ZMP cannot. Giving the acceleration in Eq.(14)∼(16), however, to the COG with \( p_Z \) and \( f_z \) substituted for \( \text{ref} \ p_Z \) and \( \text{ref} \ f_z \) respectively, it becomes manipulable indirectly. Integrating it, the referential COG velocity \( \text{ref} \ ˙p_G \) is calculated.

Suppose the referential COG velocity is given as \( \text{ref} \ v_G \), \( \text{ref} \ p_Z \) is decided as an actuating value by any common controlling method for inverted pendulums in order to let \( ˙p_G \) converge to \( \text{ref} \ v_G \). In the case that \( \text{ref} \ p_Z \) is out of the supporting region, just the same way with that in 3.3. is adopted.

\( \text{ref} \ f_z \) should be decided independently from \( \text{ref} \ p_Z \). Adequate decision of this value enables the robot to act more adaptive and responsive, or even to transit seamlessly from/to contact phase to/from aerial phase. Here, we decide \( \text{ref} \ f_z \) as:

\[
\text{ref} \ f_z = K_{Pz}(\text{ref} z_G - z_G) + K_{Dz}(\text{ref} ˙z_G - ˙z_G) + mg \tag{24}
\]

\( K_{Pz} \) and \( K_{Dz} \) are decided in accordance with the current contact state and the motion scheme. The COG height \( z_G \) converges to \( \text{ref} z_G \) without overshoot when \( K_{Pz} \) and \( K_{Dz} \) satisfy the following condition.

\[
K_{Pz} > 0, \quad K_{Dz} > 0, \quad K_{Pz}^2 - 4K_{Dz} > 0 \tag{25}
\]

Lifting-off motion is achieved by giving enough velocity and acceleration against the gravity to the COG. Then, \( K_{Pz} \) and \( K_{Dz} \) are designed as:

\[
K_{Dz} = 0, \quad K_{Pz} = \frac{2mgz_H}{z_d^2} \tag{26}
\]

where \( z_H \) and \( z_d \) is a planned maximum height and a planned stooping depth from \( \text{ref} z_G \) respectively. Conversely, in order to absorb the impact at the moment of...
touchdown, \( K_{Dz} \) and \( K_{Pz} \) are designed as:

\[
K_{Dz} = 0, \quad K_{Pz} = \frac{m \dot{z}_{G-}}{z_d} \tag{27}
\]

where \( \dot{z}_{G-} \) is the falling speed immediately before touchdown, and \( z_d \) is a planned stooping depth after touchdown. Fig.6 illustrates this modelization of VIIP.

4.2. Synergetic Generation of Whole-body Motion

Resolution of \( \dot{p}_G \) is done by arranging (22) as:

\[
\frac{1}{2} \dot{\theta}^T W \dot{\theta} \rightarrow \text{min.}
\]

subject to

\[
\begin{align*}
J_c \dot{\theta} &= c \\
J_U \dot{\theta} &= u
\end{align*}
\]

and the solution is

\[
\dot{\theta} = W^{-1} J_U^T (J_U W^{-1} J_U^T)^{-1} u \tag{29}
\]

The success of this simple management of such the complex system underlies the same principle with synergetics known in a biological field; many natural systems with a large number of DOFs act in accordance with constraints which reduces the apparent DOF.

4.3. Simulation

![Kinematic structure, size and mass of the robot](image)

**Figure 11:** Kinematic structure, size and mass of the robot

We confirmed the validity of the proposed through some computer simulations as i) the COG displacement on both feet, ii) stepping motion and iii) one-step-forward motion and walking. Fig.11 shows kinematic structure, size and mass properties of the robot model.

A stepping motion with impulsive disturbance has also been examined. Fig.7 is a snapshot. The robot moved adaptively to cope with disturbance. Fig.8 is the loci of \( p_G \), \( \dot{p}_G \), \( p_Z \) and \( \dot{p}_Z \) with respect to \( \Sigma_0 \), which shows that \( p_Z \) follows \( \dot{p}_Z \) with a good accuracy.

A jumping motion by HOAP-1 model is also realized in a simulation. Fig.9 is a snapshot of the motion. And the loci of both COG and ZMP are shown in Fig.10. We’ve verified that the method works properly and the stable jumping motion is achieved.

5. Conclusion

COG Jacobian to evade dynamical complexity of the legged systems and handle them is derived. A stabilization method based on DTAD and VIIP model control to realize responsive motion are introduced as its applications. They are achieved through ZMP manipulation, which is also enabled with COG Jacobian.
